2505. STUDIES ON THE ADAPTATION OF METABOLISM. VIII. THE LATENT PERIOD OF EXPLANTED TISSUES OF RATS ADAPTED TO INTERMITTENT STARVATION - Horeckova E., Poupa O., and Fabry P. Lab. of Physiol. and Pathophysiol. of Metab., Inst. of Human Nutr., Prague PHYSIOL. BOHEM. 1959, 8/1 (15-21) Graphs 2 Tables 3

The latent period of explanted striated muscle and liver tissues of rats adapted to intermittent starvation is significantly reduced in comparison with the latent period of the same tissue of control animals. An increase of substances important for active growth of explanted tissues (glycogen and proteins) in the livers and muscles of adapted animals may be responsible for this effect. Changes in the metabolism of the whole animal as well as direct cellular changes may be present, but only the former have hitherto been proved. Whatever the mechanism of this phenomenon may be, it is noteworthy that changes established during the adaptation of the whole organism appear in primary explants of its tissues. Hahn - Prague

ABSTRACT: Cells have two kinds of vital activities: an internal and an external one. These two kinds of activities can best be investigated in cell cultures. The author investigated the adaptation responses of organisms to lowered temperature at the level of cells. These cells have been cultivated for extended periods *in vitro*, that is without access to regulative actions of the whole organism. Temperature of 4°C was used: cells originating in human cells Detroit 6, and from epidermic carcinoma HeLa in humans, and in mice were studied. Cultures were kept at 4°C for some time, and then returned to 36-37°C. Mice cells sur-

Card 1/2

L 2059-66

ACCESSION NR: AF5027290

survived for 6 weeks; Detroit for 5 and HeLa only for 2. From surviving cells lines were prepared showing increased resistance to cold. Culture cells have higher chromosome numbers than those in intact organisms, usually between triploid and tetraploid numbers. Cold-tolerant cells showed further increase in chromosome numbers; this agrees with the fact that arctic flora have cells with higher chromosome numbers than that in a moderate climate.

ABSTRACT: The latency period in ontologically grown cells as a function of the age of the donor is discussed. Growth of cells in vitro, after they were separated from the factors of their surroundings was investigated; tissues from rats of various ages were used. The composition of the emigrating cells, and the fine structure of the cellular protoplasm change. In explantates from young animals polymorphonuclear cells prevail; in adult and old animals mononuclear ones. These differences persist even after complete separation from intracellular materials. Cells that were grown in

Prague, Ceskoslovenska Fisiologie, Vol 15, No 2, Feb 66, pp 105-126

Abstract: Subcutaneous fibroblasts from mice were used to prepare a culture exposed repeatedly to cold. This results in replication without division of the cytoplasm, so-called endoreduplication, which was manifested after it was removed from the cold, during the first mitosis by the existence of diplochromosomes in cells. Endoreduplications were known previously to be due only to radiation effects. 4 Figures, 6 Western, 1 Czech reference. Submitted at "16 Days of Physiology" at Kosice, 29 Sep 65.

"Adaptation of Animal Cells to Higher Temperatures."

Prague, Ceskoslovenska Fysiologie, Vol 15, No 2, Feb 66, p 107

Abstract: A strain from mice fibroblasts L was exposed to 42°C and cultivated at 36°C. Resistance of these cells to 42°C temperature was compared to that of normal cells and of cells adapted to cold. The cells adapted to heat had best resistance to high temperature; those adapted to the cold, worst. The same strains of mammal cells may be adapted either to cold or to heat, but cells adapted to cold do not tolerate heat. 1 Figure, 2 Western, 1 Czech reference. Submitted at "16 Days of Physiology" at Kosice, 30 Sep 65.

TITLE: Consideration of external effects in the inspection of high structures during various stages of construction

SOURCE: Geodezia es kartografija, no. 2, 1966, 110-120

TOPIC TAGS: general construction, civil engineering

ABSTRACT: The author describes his experiences regarding the effects of some external factors affecting the inspection of tall structures having small foundations during various stages of construction. These effects are mainly meteorological in nature (sun, wind, etc.). With the aid of techniques developed for this purpose it is possible to eliminate the effects of these factors and to determine accurately the verticality of the structure's axis and the configuration of its outline. These techniques were described and the operations involved in their use were discussed. Orig. art. has: 7 figures, 43 formulas and 1 table. [JPRS: 36,457]

TITLE: Investigation of movements of buildings caused by external factors

SOURCE: Geodezia es kartografija, no. 3, 1966, 194-200

TOPIC TAGS: wind, civil engineering, structure stability

ABSTRACT: Means for investigating movements of buildings by external factors such as unidirectional solar illumination, wind, and the like, were described. The techniques were employed in the study of the movements of the chimney stack of Danube-Shore Thermal Power Plant (Dunamenti Hoeromu) [location not given]. This chimney is 200 m. high. The daily movements caused by the sun and winds from various directions were determined geodetically. The results were presented and discussed.

Holecy, *Eléktrotechnik und Mechanik der Ungarischen Technischen Universität Budapest* (Proceedings of the Technical University for Architecture, Civil and Transportation Engineering), Vol. 4, 1968, No. 2, pp. 3-24, 7 figs., 3 tabs.

The computation of indirect distance measurements by resection can be reduced to the solution of a linear equation system with two unknowns. This computation can be done very quickly with a dual computer. Having made the necessary adjustments and turning the result counters to identical values according to the well-known principle of the dual computer, the unknowns of the equation system will appear in the result counters and in the revolution counters. The constructive solution of the Pothenot problem (resection) originating from Cassini can be applied to double and even multiple resections. The essence of the problem is that by inserting reference points the multiple resections can be gradually transformed into resections always containing one unknown point less until the case of simple resection arises. By this construction even multiple resections can be reduced to computations of intersections only, the more suitable for mechanical computation since the use of trigonometrical charts is reduced to a minimum. The time of computing with a dual computer is considerably reduced inasmuch as coordinates of the points can be computed simultaneously by pairs. Depending upon the number of unknown points to be computed by multiple resection the number of the required points of reference and of the intersections can be determined in advance permitting conclusions as to the volume of computation involved.

TITLE: Vacuum Distillation of Lead Matte

PERIODICAL: Hutnické listy, 1959, Nr 9, /pp 796-798

ABSTRACT: On the basis of laboratory tests, the authors have proved the possibility of vacuum distillation of lead matte for the purpose of separating lead and zinc from copper. 97.8% of the lead and 99% of the zinc are transferred into the condensate and the obtained condensate represents a lead-rich concentrate which can be used for lead manufacture, whilst the produced matte is rich in copper with a very low content of lead and zinc which can easily be processed into converter copper without involving high losses.

TITLE: Reverberatory furnace for continuous production of converter copper

SOURCE: Hutnické listy, no. 3, 1966, 226-227

TOPIC TAGS: copper, metallurgic furnace, refractory, molten metal, metal melting

ABSTRACT: The article is a summary of Czechoslovak Patent Application Class 40a, 15/04, PV 5774-63, dated 22 Oct 63, improving Czechoslovak Patent # 104 449. The invention covers a feature of the design of the reverberatory furnace; part of the refractory lining extends to within 5 - 20 cm from the level of the molten metal. The lining has an inner hollow space, through which the fine grain ore charge together with the oxidizing gas are introduced in the furnace. The advantage of such an arrangement is that the charge enters a part of the furnace which is at the maximum temperature, where it melts immediately, avoiding any dust formation. Because of the proximity of the gas inlet to metal a lower gas pressure can be used than in other furnace designs.

TITLE: Radio range finder for measuring small distances

PERIODICAL: Referativnyy zhurnal. Astronomiya i Geodeziya, no. 4, 1962, 39,
abstract 4G237 P (Polish patent, cl. 21 a⁴, 48/62, no. 44,375,
27.04, 61)

TEXT: A radio range finder is patented for measuring distances up to 3 km with an error of $10^{-5} D \pm 5$ cm. The range finder consists of two radio stations mounted at the ends of the line being measured. The stations operate at the 3-cm band. The two-side ultrashort-wave telephone communication is provided between the station operators. The frequency difference between the station klystron generators is constant and equal to 36 Mc. The basic standard frequency of the system is frequency $f_1 = 15$ Mc, stabilized by quartz at the auxiliary station. At the main station, fluctuations of the carrier frequency are modulated by one of the two frequencies: $f_g = f_1 - 1.5$ kc and $f_d = f_1 + 1.5$ kc. Oscillations of the 1.5-kc frequency are transformed at the auxiliary station into repetition pulses of 3 kc. Upon returning to the main station the series of

Card 1/2 *VX*

Radio range finder for measuring ...

S/035/62/000/004/053/056
A001/A101

pulses is separated from sine oscillations, and phase shift which serves to determine the line length is measured with a phasometer. The repetition frequency of 3 kc is selected with the aim to reduce the error in reading the phase and to distinguish the reflected signal from the sinusoidal signal of the main station. The carrier waves of the two stations are polarized along the vertical, which, in the authors' opinion, reduces measurement errors caused by wave reflection from the ground. Special attention is paid to stability of frequency differences: $f_d - f_1 = 1.5$ kc; $f_1 - f_g = 1.5$ kc. Prior to measurements it is recommended to tune the frequencies f_d and f_g , as well as to compare the frequency difference with the standard one.

AUTHOR: Holejko, Krzysztof

TITLE: The physical principles of geodetic short distance measurements by means of electronic devices

PERIODICAL: Archiwum elektrotechniki, v. 10, no. 3, 1961, 743-761

TEXT: This article provides an introduction to geodetic short distance measurement by calculating the phase shift of the electromagnetic waves emitted from two points A and B, the distance between which is sought, from the following formula

$$l = AB = \lambda \Psi = \frac{c}{f} (n + \phi) \quad (1)$$

(λ - wave length, Ψ - phase shift, c - velocity of wave propagation, f - frequency, ϕ - phase meter reading as a fraction of Ψ .)

Card 1/3

The physical principles of ...

P/019/61/010/003/004/008
D265/D305

Given c and f the problem is confined to finding the values of n (n - total number of wave lengths between A and B). Two methods of finding the phase shift are described: 1) Measurement of the carrier phase shift consisting of two systems of transmitters of fixed frequencies and receivers connected to a common antenna and situated at each end of the measured distance. The phase meter readings are taken at one end. 2) In the second method the phase shift measurement of the modulating signal is superimposed on a carrier. At both ends of the measured distance the microwave generators work at definite frequencies, chosen so that their differences are equal to the frequency to which two resonant amplifiers and receivers are tuned. The generators' frequencies are modulated to the voltage frequency and to the frequency of a separate generator. The comparison of phases is obtained at the receivers' ends. 3) For both methods described the factors influencing the phase meter readings are discussed and the final formulae are established for each case for the value of the phase shift after analytical considerations. In order to find the number of wave lengths - n - the method of calculation is devised whereby the coefficients a ,

TITLE: The influence of ground reflections on the accuracy
of some electronic geodetic distance meters

PERIODICAL: Archiwum elektrotechniki, v. 10, no. 4, 1961, 855-875

TEXT: The author refers to his previous publication (Ref. 7:
Arch. elektro. v. 10, no. 3) and describes in this paper the influence
of ground reflections on the accuracy of geodetic distance measurements
by the phase shift of a sinusoidal standard radio frequency wave super-
imposed on an electromagnetic carrier. Errors are due to the fact that
the measurements are taken at a certain distance above the ground and
the phase shift, indicated by the phase meter, includes the wave reflec-
ted from the ground. The ground reflection error is calculated on the
basis of the image theory and is discussed as a function of the equip-

width and the wavelength of the standard and carrier signals on magni-

Card 1 / 2

P/019/61/010/004/003/006

D265/D303

The influence of ground ...

tude of the error is studied in detail. An analysis is given of the relationship between the ground reflection error and the plane wave reflection coefficient, the distance measured and the height at which the instruments are placed. It is concluded that in certain cases this error can be diminished by changing the wavelength of the carrier or by changing the height at which the instruments are fixed. There are 10 figures and 11 references: 5 Soviet-bloc and 6 non-Soviet-bloc. The 4 most recent references to the English-language publications read as follows:

Kuropieska J., Holek S. A Rapid Method for Determining Soap Content
in Consistent Greases

"Opracowanie szybkiej metody oznaczania zawartości mydła w siłach
stacyjnych" (Prace Inst. Naft. No. 30). 1954. Stalnogród. PWG, 11 pp.,
10 figs., 6 tabs.

A rapid method for determining the soap content in consistent greases is described. The method consists in dissolving a private sample in a mixture of ethyl alcohol and benzene (1:2) and in back titration of soaps by the 0.1 n alcohol solution of HCl according to the reaction: MeR HCl = MeCl + H₂R. Admixtures of carbonate present in the grease are removed from the solution by filtering. Free bases in sodium greases are removed or changing them into carbonate and by subsequent filtering, in calcium greases, however such bases are determined separately and subtracted from the general results. Titration is carried out by the conductometric method. The method gives approximate results based on the average acid number of fatty acids. If the kind of acids comprising the soap is known, the results are exact. Deviations in partial determination do not exceed 0.4 per cent of fatty acids in relation to the determination of the average about 1 per cent of the lower result. The grease, being on the average about 1 per cent with the actual soap content and with results obtained by other methods is satisfactory. The duration of the determination is from 5 to 7 hours, depending on the rate of dissolution of grease.

ABSTRACT : For a rapid determination of CN⁻ in alkaline solutions use is made of direct titration of CN⁻ with a solution of NiSO₄ using rubanic acid(I) as an indicator. Since I is unstable in ammoniacal solutions the titration end-point is determined by a spot test on paper. In the determination of CN⁻, there are added to 1 ml of the solution being analyzed 10 ml NH₄OH (1:1) and approximately 50 ml water, and titration is carried out with a solution of NiSO₄ (10 g NiSO₄.7H₂O dissolved in 1 liter water; 1 ml of this solution corresponds to 3.7 mg CN⁻). Titration end-point is determined by placing a drop of the titrated solution on paper impregnated with 0.5% ethanol solution of I.

Abstract: Degree of decolorization of the red solutions containing complex of antipyrine (Ant) and Fe^{3+} with ions of F^- has been investigated. It was found that the greatest decrease in optical color density of colored solution takes place at 2 pH and at the antipyrine concentration of 4×10^{-2} M. This change occurs as a result of an interaction between the $\text{Fe}_2\text{Ant}_3^{6+}$ and the F^- ions with the formation of a colorless Fe F^{2+} complex. Photometrical

Abstract: determinations of F^- are made, therefore, possible by utilizing the degree of decolorization. This has been done under similar conditions ($465\text{m}\mu$), in the F concentration range of 35-300 μ , using 25 cc of the final solution, and obtaining results whose relative error varied between -3.1 and +4.6%. The optimum concentration of Fe^{3+} investigated was determined from samples containing: 10.75×10^{-6} , 5.7×10^{-6} , and 3.15×10^{-6} M. The correspondingly stronger reducing agents and compounds that form stable complexes with either Fe^{3+} or F^- were found detrimental and interfering. Presence of Cl^- (in

Repair of Castings with Synthetic Resins. K. Holz. (Münchener Lloyd, 1951, 6, 6, 229-31). [In Czech]. Tests lasting six months showed that only certain bakelite resins are suitable for rendering porous castings serviceable. The resin is introduced into the castings either by a vacuum or by compressed air. Both methods are described. - G. G.
